Numerical experiments performed using the NCAR TIME-GCM

NCAR TIME-GCM¹ Simulations

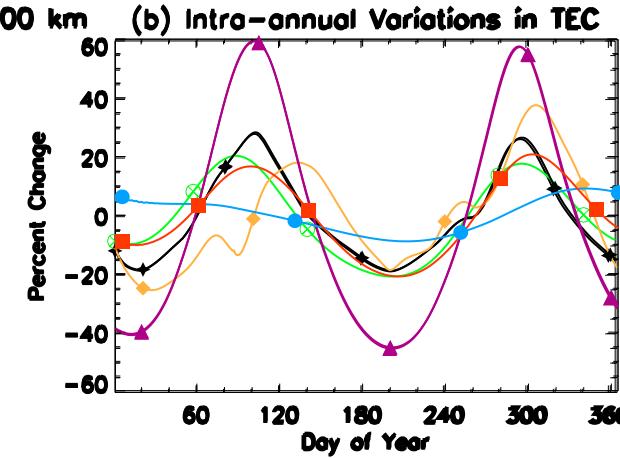

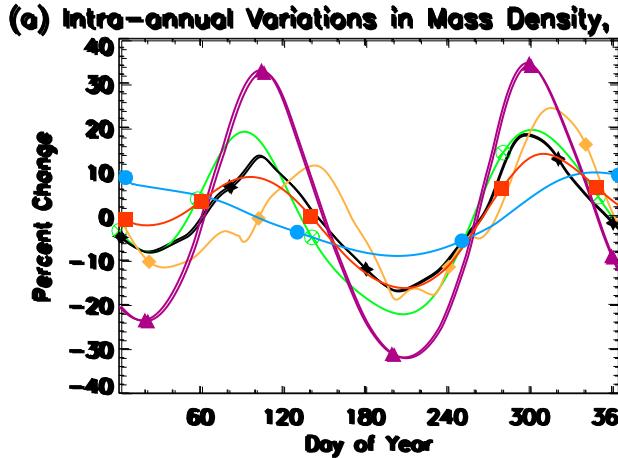

- Double resolution ($2.5^\circ \times 2.5^\circ$
Ion x lat, 4 points per scale height)
- $F_{10.7} = 110$ sfu
- Geomagnetically quiet conditions.

TIME-GCM Simulation	Tidal LBCs (TD) <i>Zhang et al. [2010a,b]</i>	Gravity Waves (GW) $\rightarrow K_{zz}$ <i>Lindzen [1981]</i>	Obliquity Angle
Standard, Full Tilt	✓	✓	23.5°

¹ National Center for Atmospheric Research (NCAR)
Thermosphere-Ionosphere-Mesosphere-Electrodynamics
General Circulation Model (TIME-GCM)

IAVs in Globally Averaged Mass Density and TEC

	Mass Density at 400 km		TEC	
TIME-GCM Simulation/ Observed Climatology	Amplitude (%)	Phase (days)	Amplitude (%)	Phase (days)
Observed Climatology*	15.5	108	15.8	102
Standard, Full Tilt	12.8	114	19.7	106
w/o GW, Full Tilt	15.3	131	21.3	123
w/o GW+TD, Full Tilt	29.4	113	47.9	106
w/o GW+TD, Half Tilt	9.5	116	16.2	111
w/o GW+TD, No Tilt	1.5	142	2.4	133

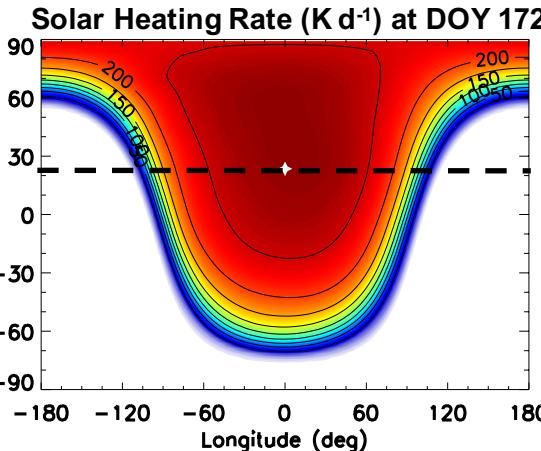

No GWs →
 K_{zz} is seasonally-invariant →
T-I SAO is still present

No Waves but Half Tilt →
TSM weaker →
T-I SAO weaker

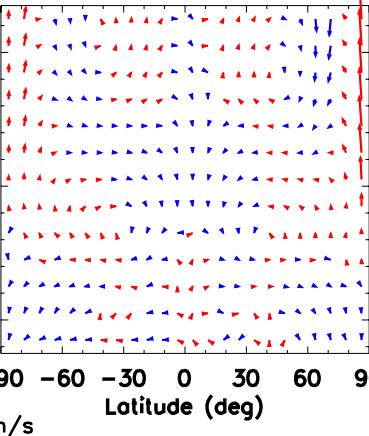

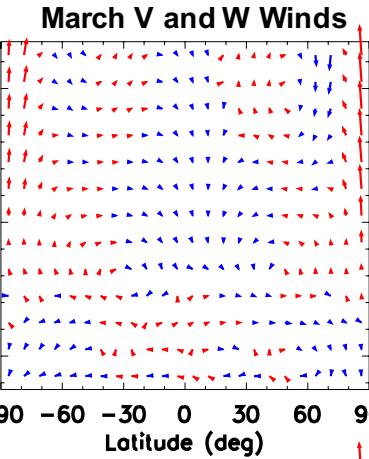

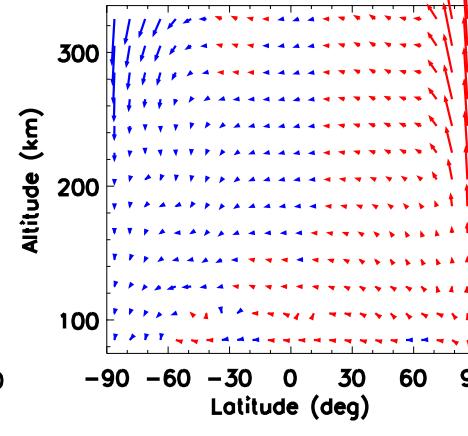

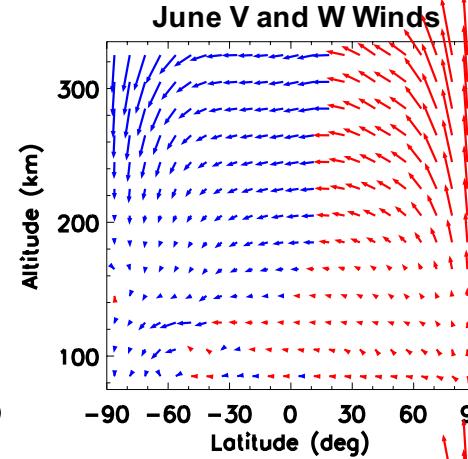

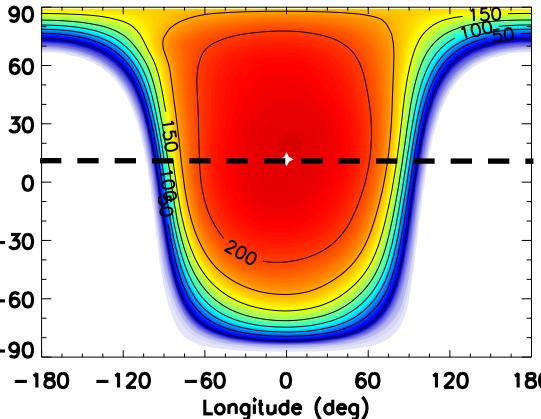

No Waves and Tilt →
No TSM →
Very Small T-I SAO

Earth's obliquity drives strong interhemispheric flows at solstice

Full Tilt (w/o GW+TD)

Half Tilt (w/o GW+TD)

In summary:

- Stronger temp/press. gradients →
- Stronger interhemispheric transport (or TSM) →
- stronger T-I SAO

Seasonal Variations in the Vertical Transport of O and N₂

Thermospheric Spoon Mechanism (steady-state balance)
advection transport \approx molecular diffusion

Individual Species Continuity Equation (*Liu, 2013*)

$$\rho \frac{\partial}{\partial t} \left(\frac{\rho_i}{\rho} \right) = -\nabla \cdot (\rho_i \vec{V}_{D_i}) + P_i - L_i - \rho \vec{V} \cdot \nabla \left(\frac{\rho_i}{\rho} \right)$$

Molecular Diffusion
Eddy Diffusion

Chemistry

Advection

K_{zz} is seasonally-invariant

Comparatively Slow
(above 100 km)

- Stronger vertical winds at solstice
- Net vertical motion at solstice:

sink of O, source of N₂ \longrightarrow T-I SAO

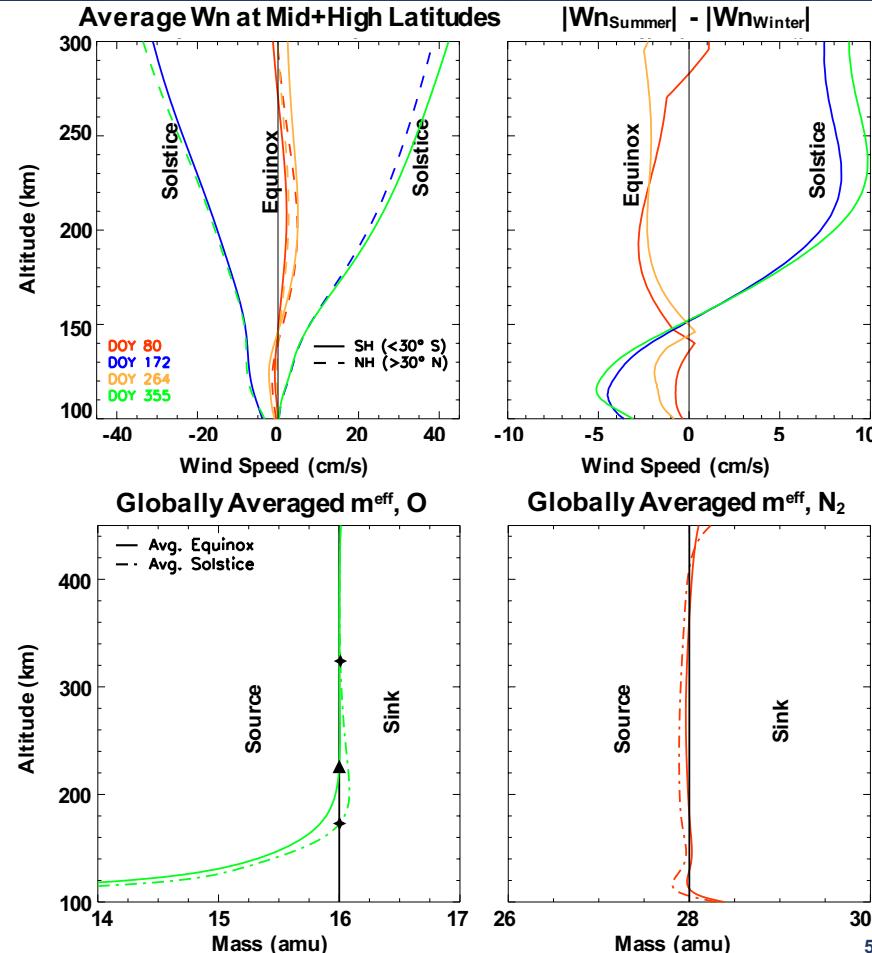

Effective Mass measures departures
from diffusive equilibrium

Equinox

- Source of O extends higher

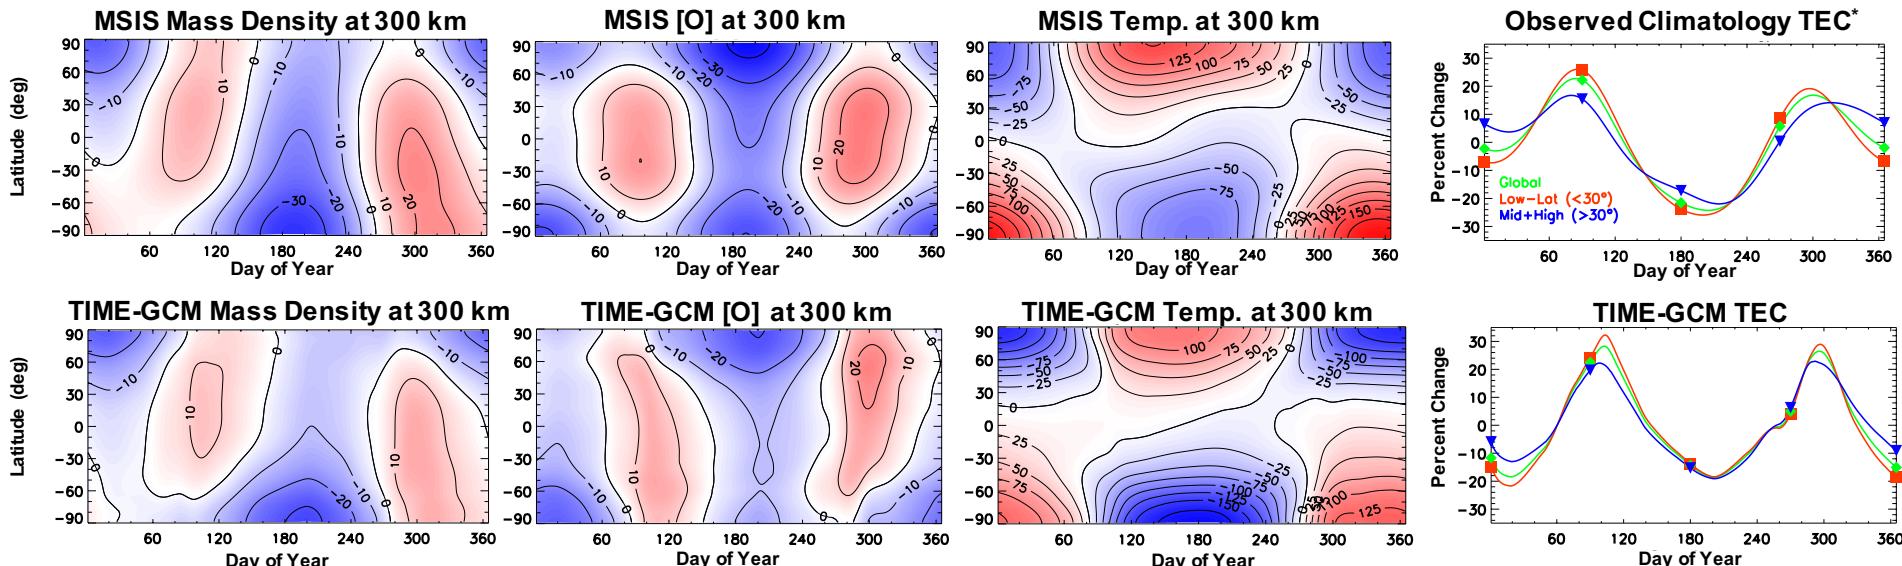

Solstice

- Clear O sink between \sim 170 and 300 km
- Larger source of N₂ (relative to equinox)

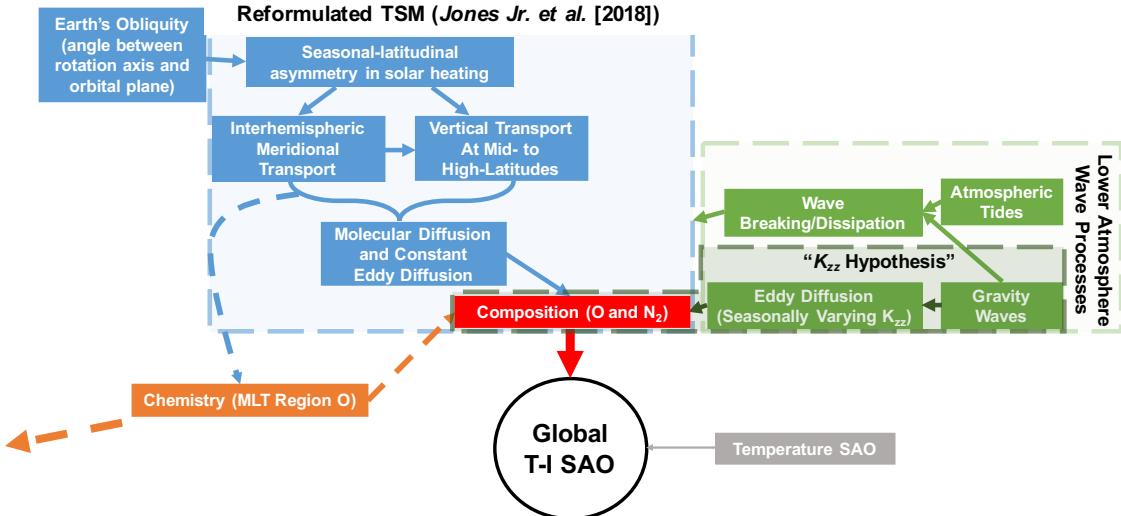

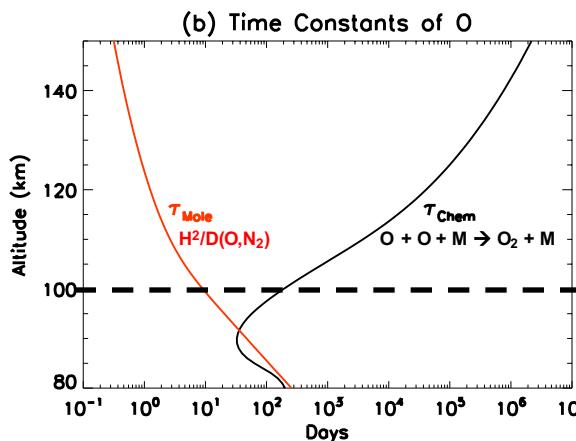

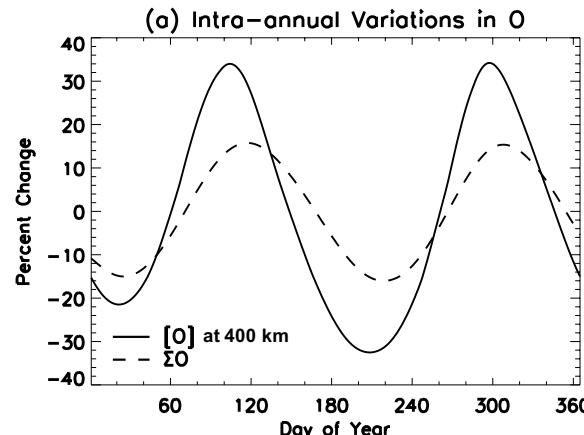

Validating spatial patterns of IAVs from the “standard” TIME-GCM

IAVs simulated in the T-I from the “standard” TIME-GCM compare well with NRLMSISE-00 and *Emmert et al. [2017]*

Phases of IAVs in mass density and [O] are approx. constant with latitude and altitude above 200 km in the TIME-GCM

Chemical Effects on the Global T-I SAO

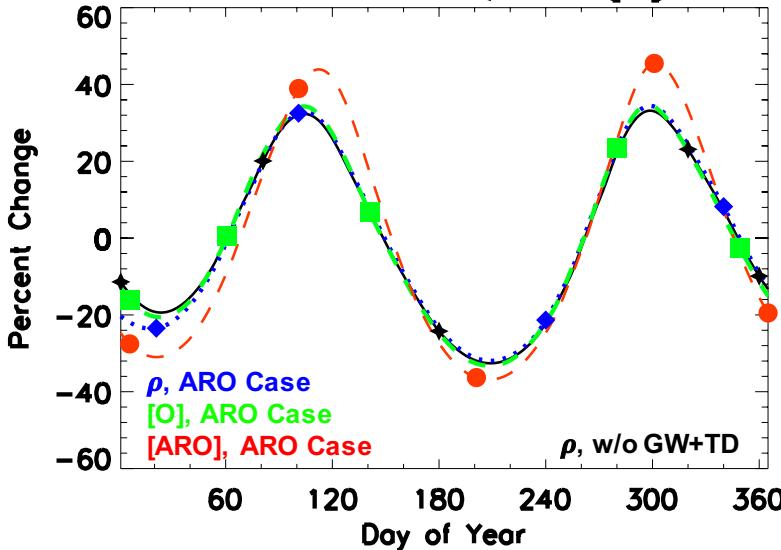

IAVs in ΣO are not flat throughout the year → chemistry contributing to T-I SAO

O chemical life times shorter than molecular diffusion in MLT → Chemistry in MLT as important as dynamics

Preliminary results: Mesospheric O chemistry damps T-I SAO

Intra-annual Variations in ρ and [O] at 400 km

w/o GW+TD Full Tilt, ARO Case

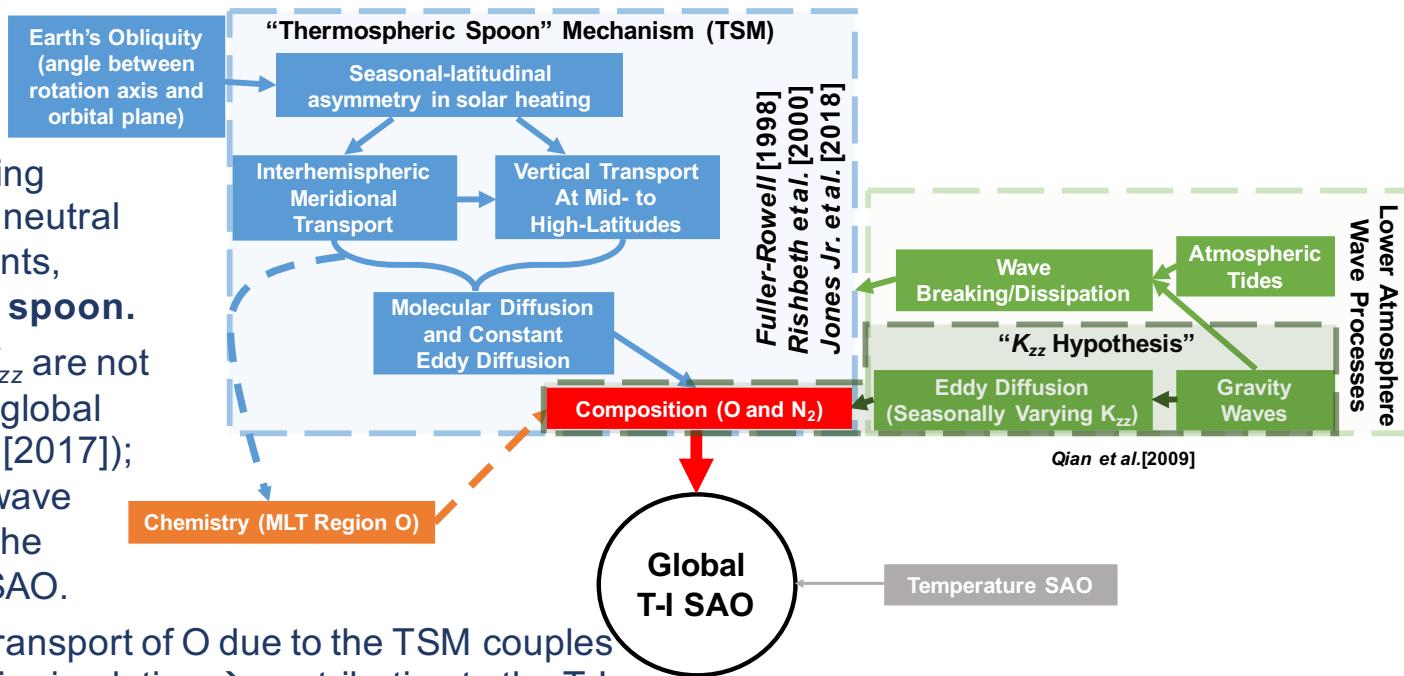

- Ar is co-opted to behave like O (e.g., same mass and diffusion)
- ARO acts like a O, but as a minor species

SAO amplitude also reduced in
TIME-GCM Standard Case

	Mass Density at 400 km		[O]		[ARO]	
	TIME-GCM Simulation	Amplitude (%)	Phase (days)	Amplitude (%)	Phase (days)	Amplitude (%)
w/o GW+TD Full Tilt	29.4	113	30.4	112	-	-
w/o GW+TD Full Tilt, ARO Case	28.1	113	29.3	112	38.0	115

Summary

- Earth's obliquity drives the global T-I SAO through seasonally varying large-scale advection of neutral thermospheric constituents, i.e., the **thermospheric spoon**.
- Seasonal variations in K_{zz} are not the primary driver of the global T-I SAO (Jones Jr. et al. [2017]); rather, tidal and gravity wave dissipation act to damp the obliquity-generated T-I SAO.
- Meridional and vertical transport of O due to the TSM couples to the upper mesospheric circulation → contributing to the T-I SAO through O chemistry.

Future Work

- Quantify the relative contributions of dynamics (or the TSM) and MLT O chemistry to the global T-I SAO in upper thermospheric mass and electron density.
- Determine the dominant driver of the annual oscillation (AO) in thermospheric mass density and ionospheric electron density.
