

The Flare Irradiance Spectral Model - Version 2 (FISM2)

An improved model of the solar spectral irradiance at
ultraviolet wavelengths

Coupling, Energetics, and Dynamics of Atmospheric Regions (CEDAR) Program 2021
June 20-25, 2021

PHILLIP C. CHAMBERLIN

LABORATORY FOR ATMOSPHERIC AND SPACE PHYSICS

PHIL.CHAMBERLIN@LASP.COLORADO.EDU

Introduction/Outline

- Solar EUV spectral Irradiance: The solar irradiance varies on all time scales, and these variations are different for all wavelengths.
- Measurements: There have been many new measurements and models of the solar irradiance over the past decade to quantify this variability.
- Space Weather Effects: Solar UV irradiance drives the Ionosphere and Thermosphere
- **FISM2: Empirical model to fill the measurement gaps, both spectrally, temporally, and spatially.**
- LISIRD: Data access for solar irradiance data has been centralized.
- Conclusions/The Future: Future instruments will improve the measurement accuracy.

Solar Irradiance – “Sun as a Star”

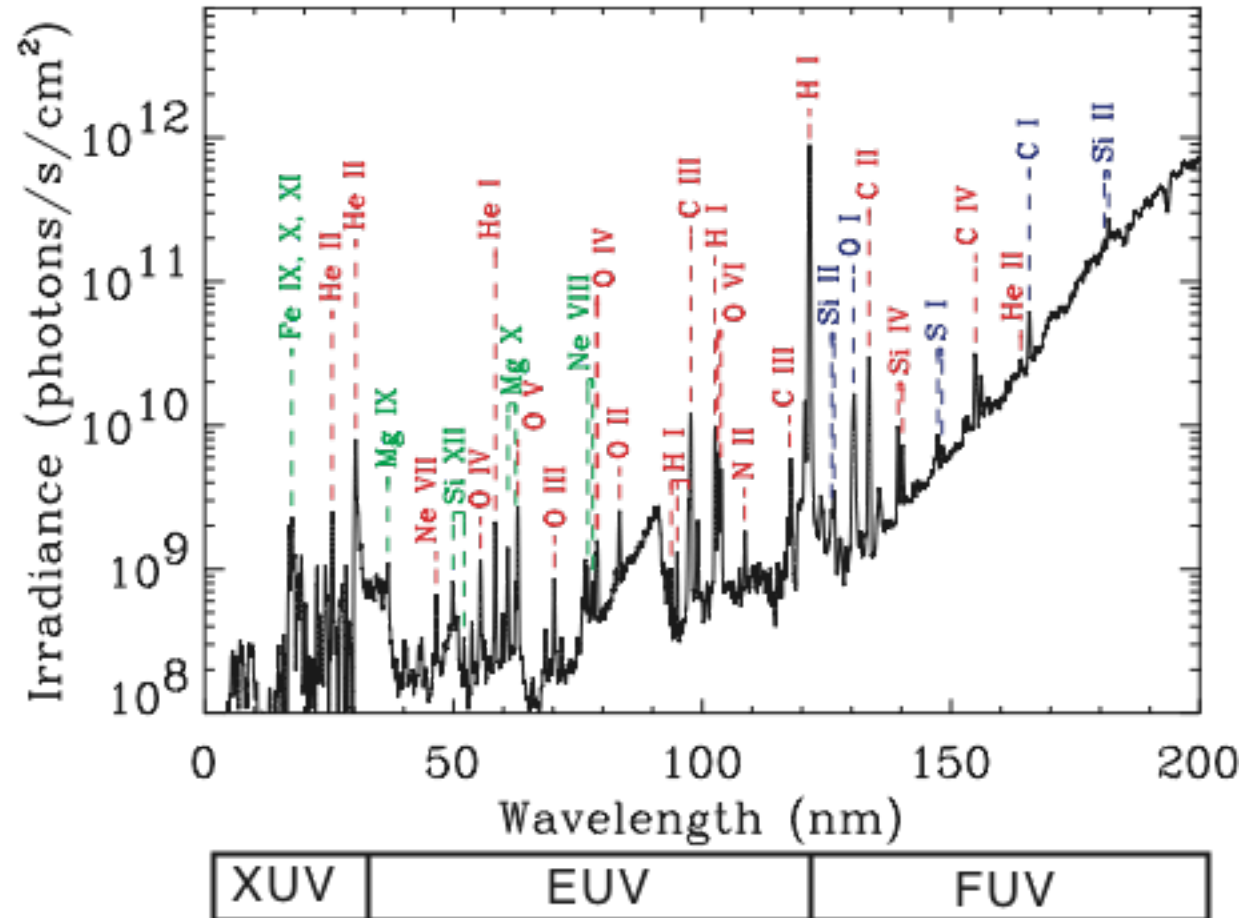

- Solar Spectral Irradiance is the amount of light from the Sun incident on the Earth
 - Units of $W/m^2/nm$
- Total Solar Irradiance is then summed over all wavelengths

Woods et al, 2009

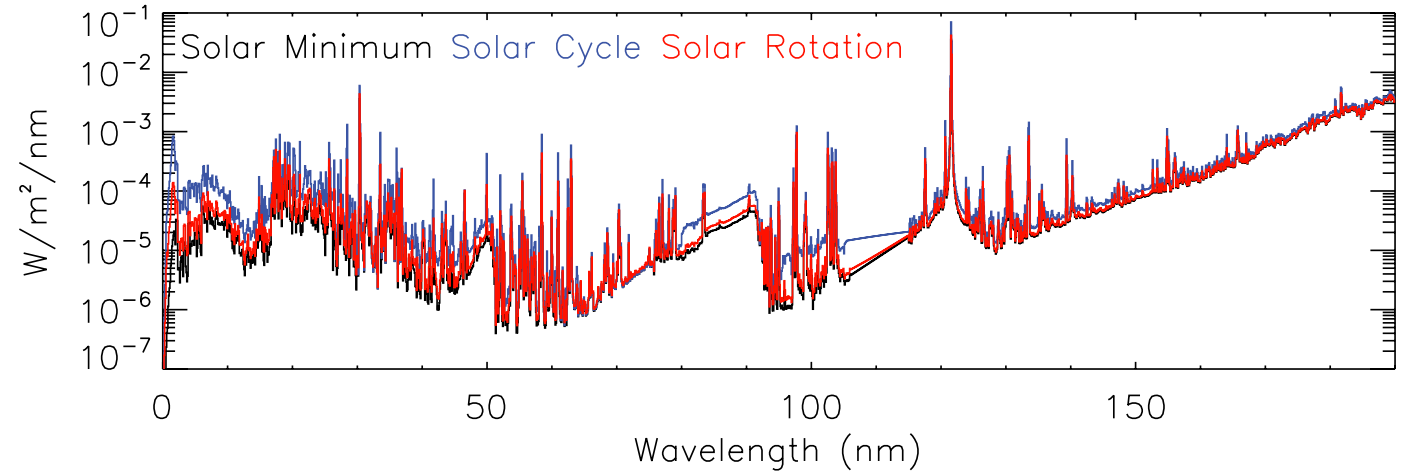

Ultraviolet Wavelengths

- Ultraviolet Wavelengths are key to Space Weather and Solar Flare variations
 - 0.1-10 nm, X-ray Ultraviolet or Soft X-ray, XUV
 - 10-120 nm, Extreme Ultraviolet, EUV
 - 121-200 nm, Far Ultraviolet, FUV
- UV contains emissions from many continua
 - Free-Free, Free-Bound, and Blackbody
- UV also contains bound emission lines
 - Formation temperatures spanning entire solar atmosphere from chromosphere, transition region, corona and flare lines
- Many ultraviolet emissions are optically thick.

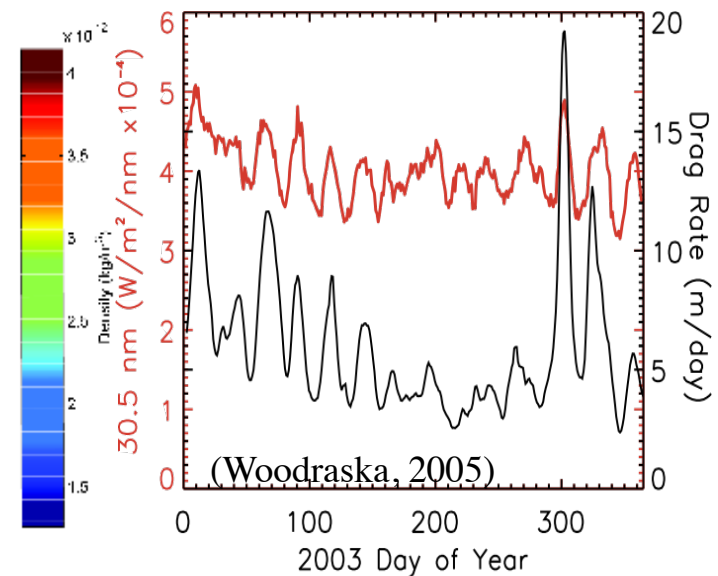

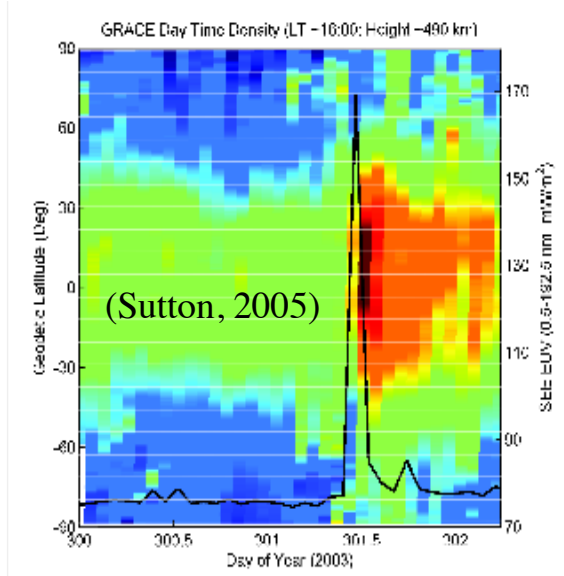

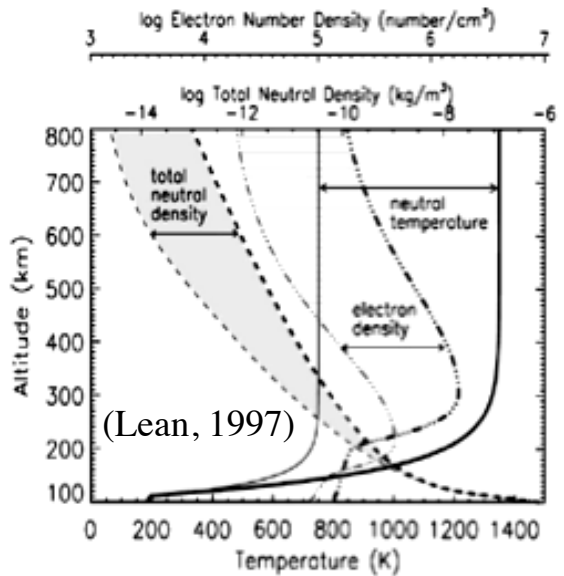

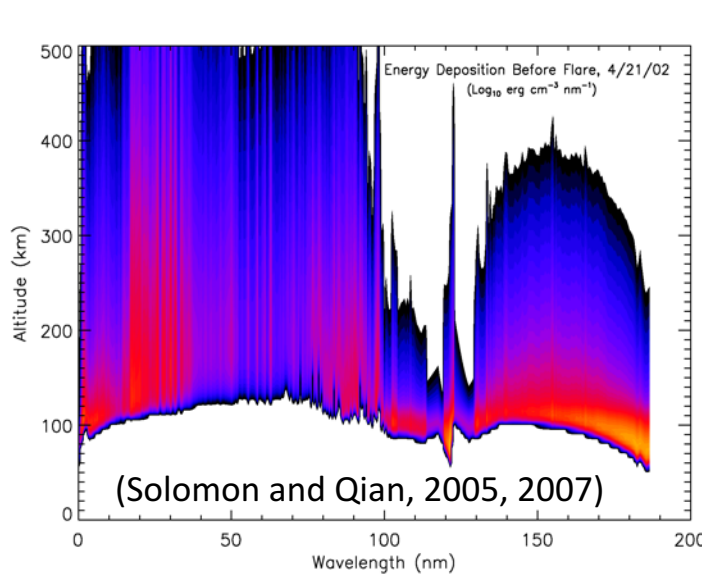

Solar Ultraviolet Variability

- Solar irradiance changes over timescales:
 - Seconds to hours due to solar flares and CMEs
 - Days to weeks due to active regions and solar rotation
 - Years and decades due to solar cycle
- Solar irradiance variation magnitude is wavelength and time scale dependent
 - I/T response is therefore altitude and time dependent

Ionosphere/Thermosphere Effects

- Solar ultraviolet irradiance is absorbed in the Earth's atmosphere, heating the Thermosphere and creating the Ionosphere initiating complex photochemistry.
- Immediate response and effects are significant in the lower latitudes.
- I/T changes affect technological systems that we are increasingly dependent on.
- Also drives changes in planetary atmospheres and lunar dust.

Measuring Solar Irradiance

- Solar spectral irradiance measurements are being made and continue to fill gaps
 - Temporally: Gaps between instruments/missions, higher time cadence
 - Spectrally: Missing wavelength ranges, higher spectral resolution
 - Full Sun: Throughout the Heliosphere (planetary, prediction)
- Future missions are looking to utilize CubeSat Platforms
 - CSIM (Launched Dec 2018), CSOL, CTIM, SunCET (proposal)
- Sounding Rockets have been critical in the development and calibration

MinXSS

GOES R+ EXIS

MAVEN EUV

SDO EVE

TIMED SEE

SORCE

FISM Version 2 (FISM2) – Now Available

- Many new measurements and studies have improved our knowledge of the Solar ultraviolet irradiance in the past 15 years

Chamberlin et al., *Space Weather*, 2020

- Biggest improvement is new measurements and proxies (*: Not in initial FISM2 release)

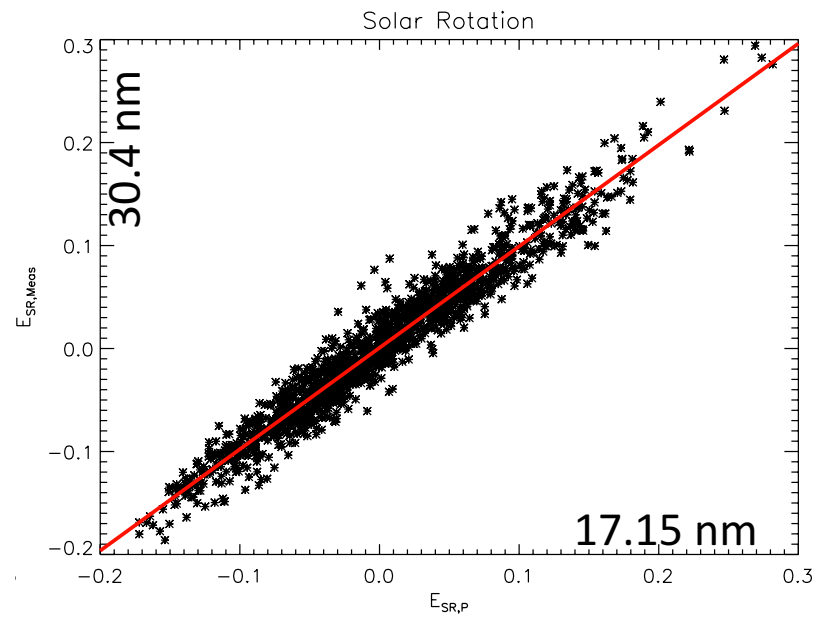

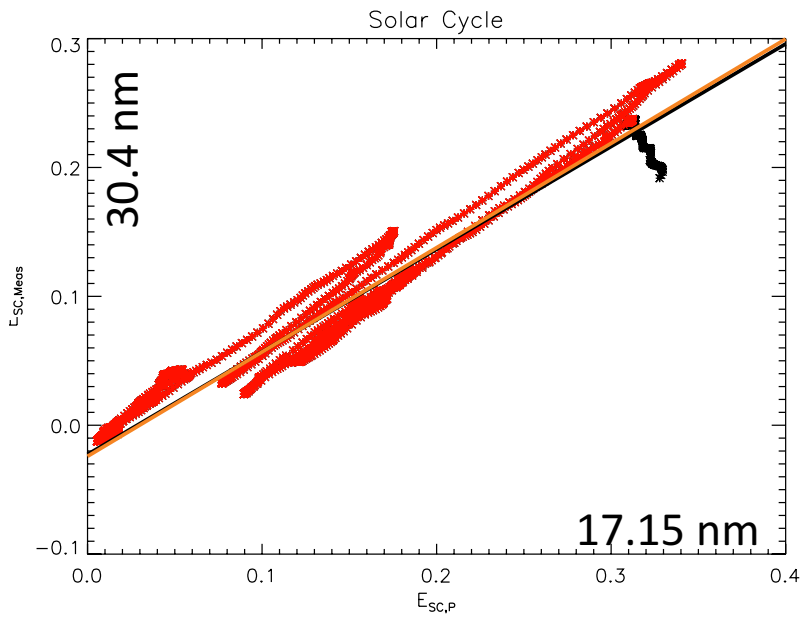

- MinXSS* (0-2.5 nm)
- SORCE XPS (L4: 0-40 nm)
- SORCE SOLSTICE (119-300+nm)
- SDO EVE (6-105 nm, and ESP)
- GOES EXIS* (XRS and EUVS)
- MAVEN EUVM (0-7 nm, 17.1 nm, 121.6 nm) – FISM-M (Thiemann et al., 2018)

- All measurements are at 0.1. nm or better and much better temporal cadence than TIMED SEE
 - FISM2 has been improved to 0.1 nm bins
 - SDO EVE has observed well over 1000 flares and SORCE SOLSTICE "hundreds"

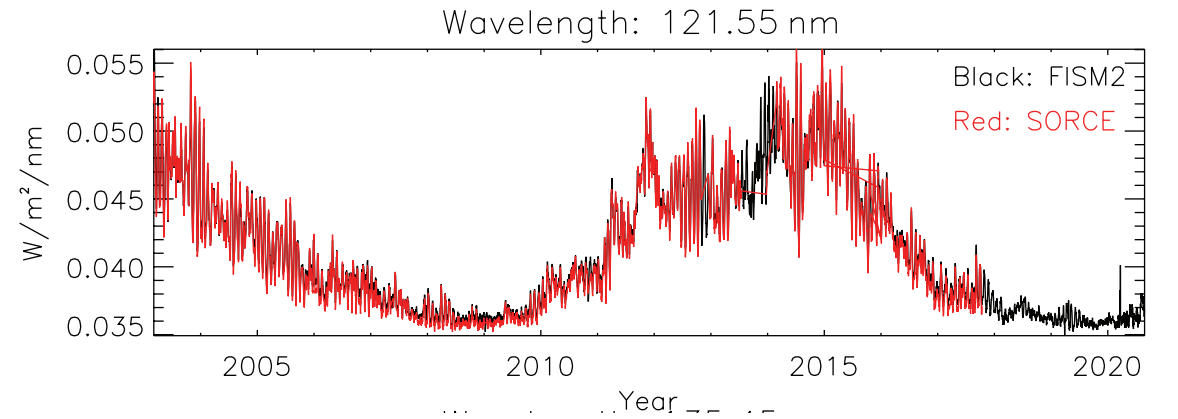

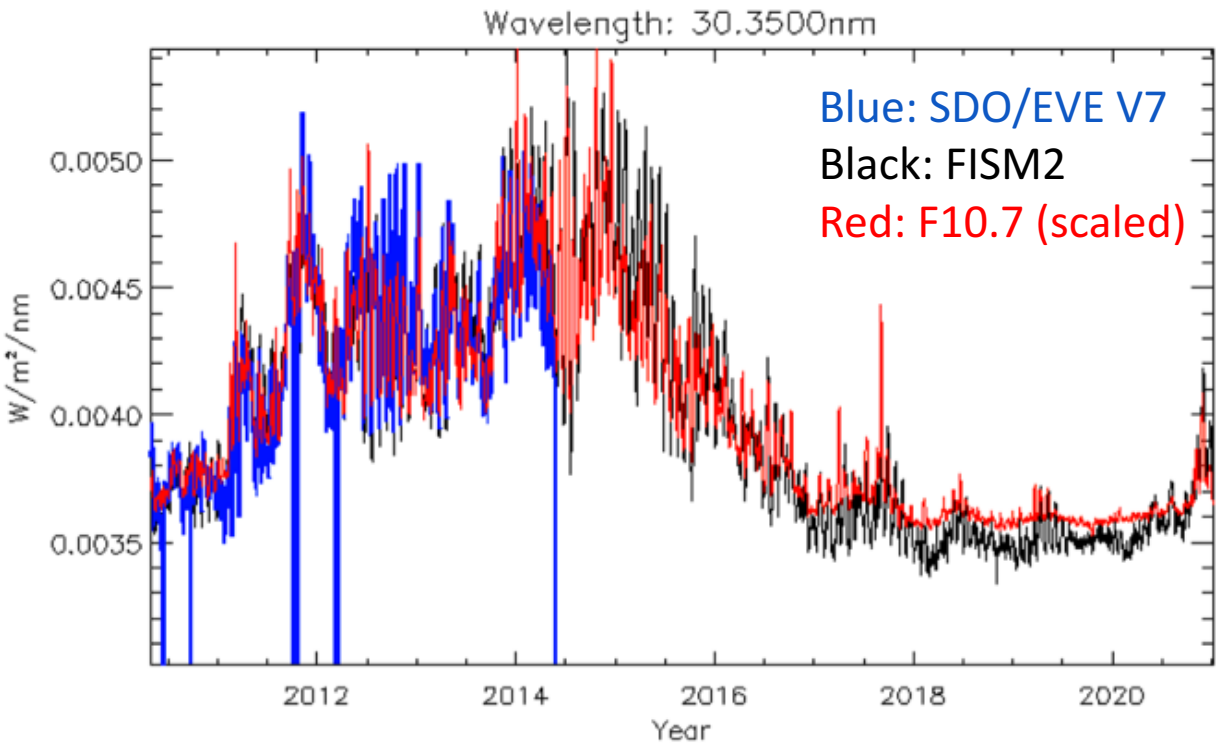

FISM2 Empirical Model – SC and SR

- FISM2 relates measurements, when available, to the co-temporal proxies.
- Whenever the proxy is available, the estimated measurement value can then be modeled.
- Full details can be found in: *Chamberlin et al., Space Weather, 2020*

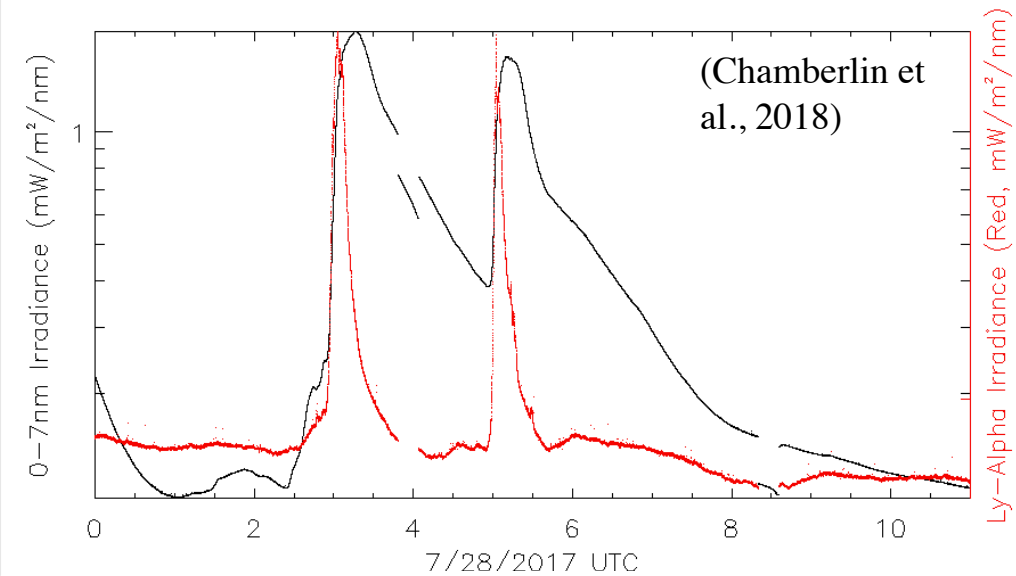

FISM2 vs Measurement Comparison

- EVE and SORCE lack full temporal coverage
- F10.7 does not fully represent the solar cycle variability, especially the solar minimum.
- Using multiple, representative proxies more accurately models the irradiance variability

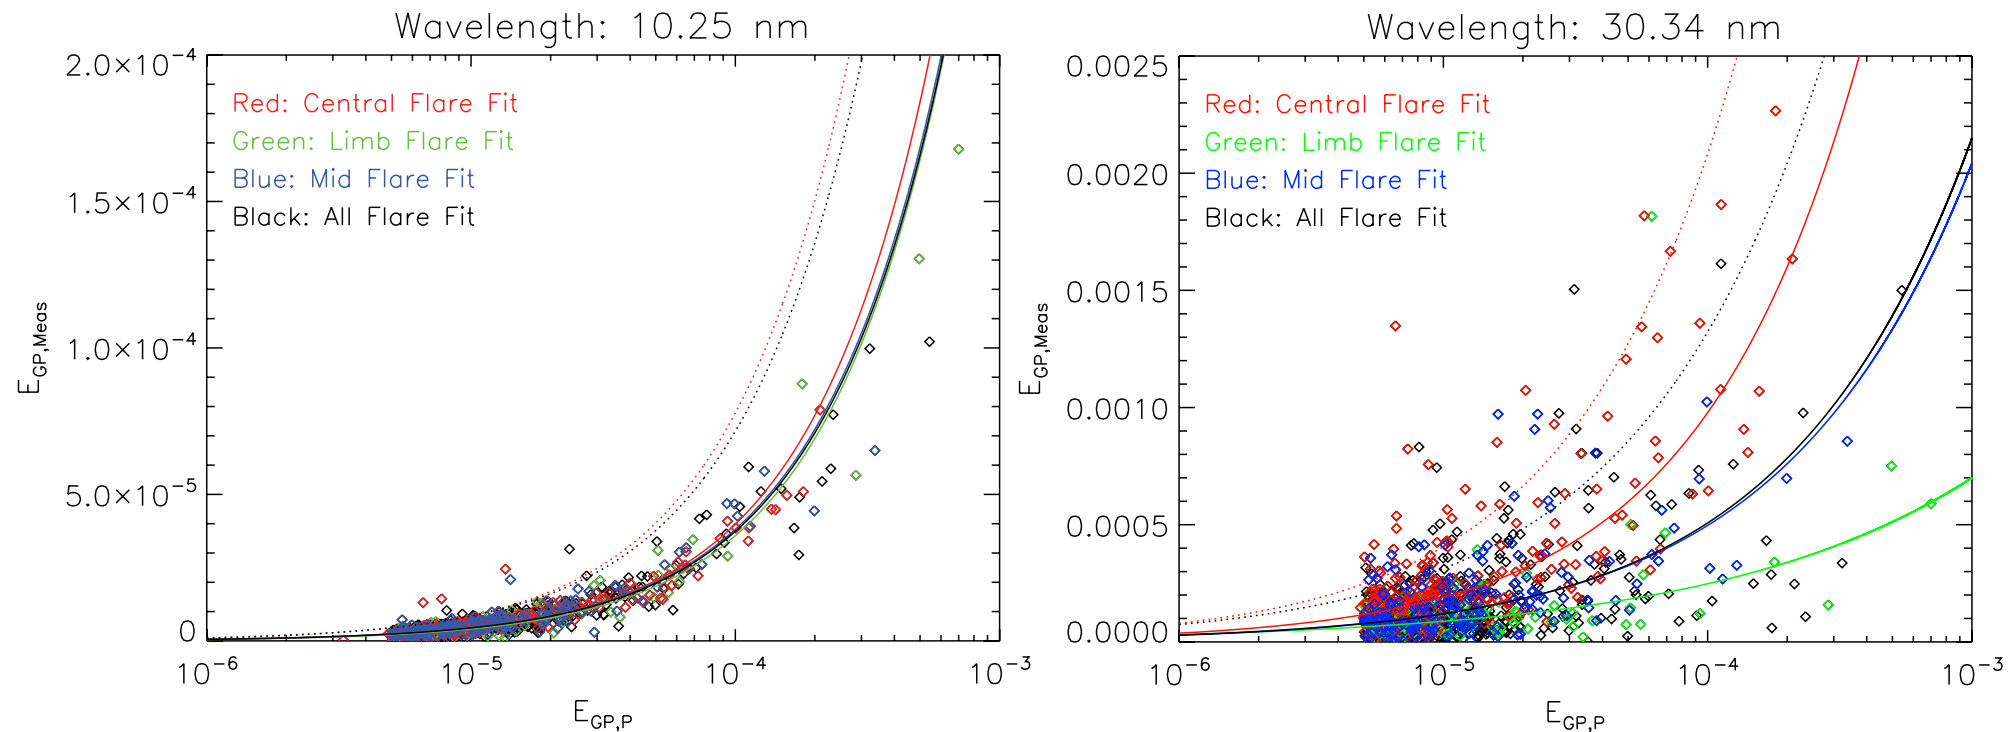

Solar Flares and UV Irradiance

- Measurements of UV irradiance can tell us about where and when energy is being deposited.
- Compute the total radiated energy from flares for Solar Physics and Space Weather studies

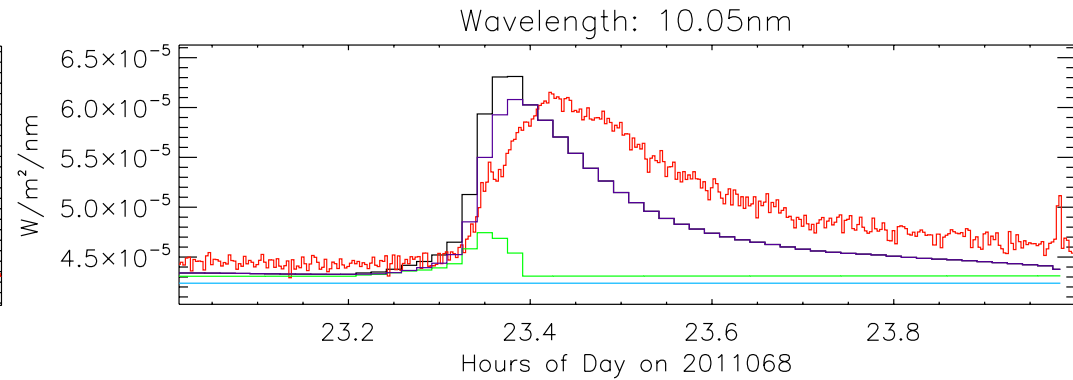

FISM2 Empirical Model – Flares

- FISM2 relates measurements, when available, to the co-temporal proxies
- Whenever the proxy is available, the estimated measurement value can then be modeled.
- Full details can be found in: *Chamberlin et al., Space Weather, 2020*

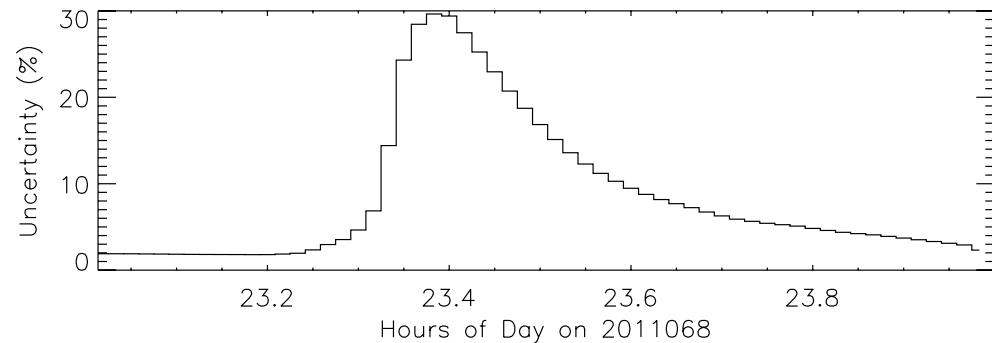

FISM2 vs Measurement Comparison

- FISM2 accurately fills in measurement gaps at 60 second cadence
- FISM2 estimates the irradiance changes due to both the impulsive and gradual phases of the solar flare.

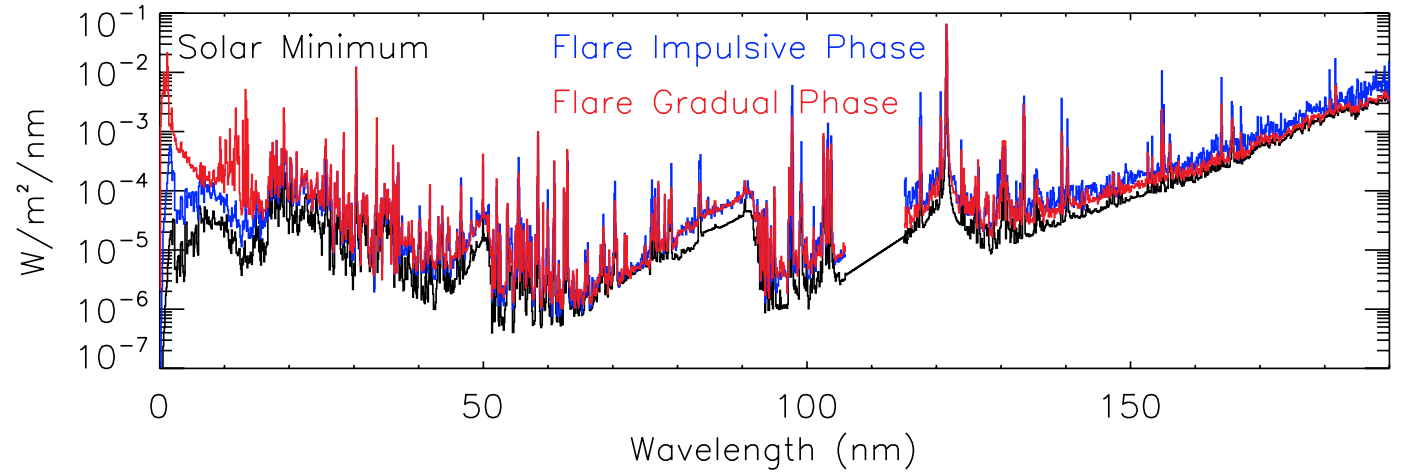

Red: FISM2
Purple: FISM2 GP
Green: FISM2 IP
Blue: FISM2 Daily
Black: SDO/EVE

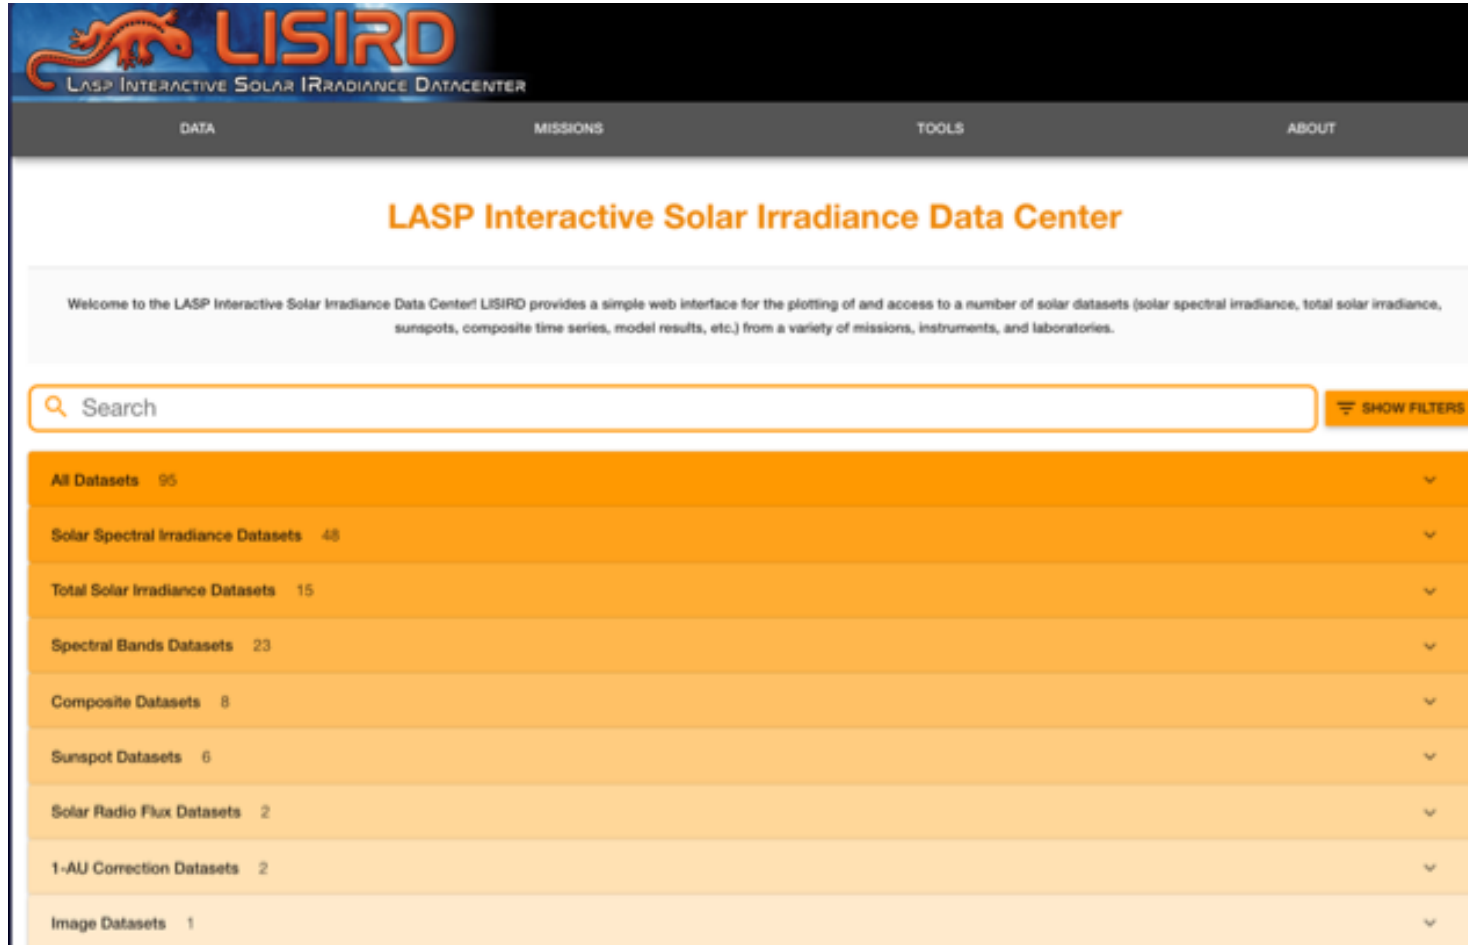

Solar Ultraviolet Variability - Flares

- Solar irradiance changes over timescales:
 - Seconds to hours due to solar flares and CMEs
 - Days to weeks due to active regions and solar rotation
 - Years and decades due to solar cycle
- Solar irradiance variation magnitude is wavelength and time scale dependent

Solar Irradiance one-stop access

LASP Interactive Solar Irradiance Data Center (LISIRD): <https://lasp.colorado.edu/lisird/>

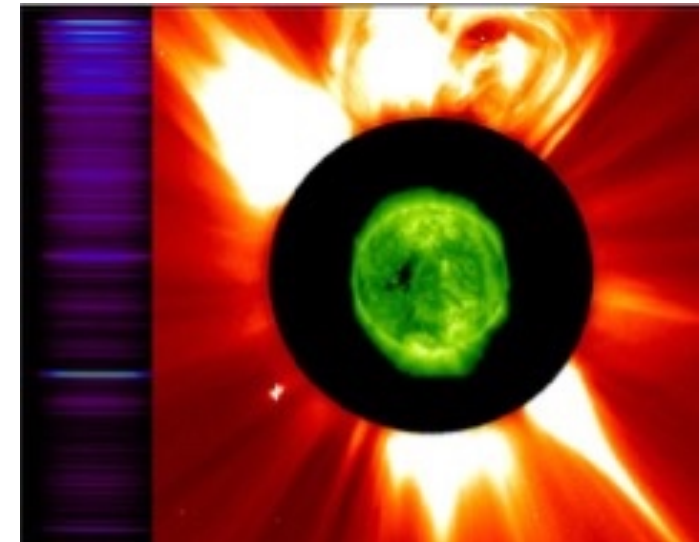

The screenshot shows the LISIRD website interface. At the top, there is a navigation bar with links for DATA, MISSIONS, TOOLS, and ABOUT. Below this is the main heading "LASP Interactive Solar Irradiance Data Center" and a welcome message. A search bar is present with a "SHOW FILTERS" button. A list of dataset categories is displayed, each with a count and a dropdown arrow.

Dataset Category	Count
All Datasets	95
Solar Spectral Irradiance Datasets	48
Total Solar Irradiance Datasets	15
Spectral Bands Datasets	23
Composite Datasets	8
Sunspot Datasets	6
Solar Radio Flux Datasets	2
1-AU Correction Datasets	2
Image Datasets	1

Conclusions

- There is a large dataset of solar irradiance measurements, both temporal and spectral
- Where gaps exist, empirical models are also improving to estimate energy inputs into Space Weather studies of the Ionosphere and Thermosphere, such as FISM2.
 - Use multiple, representative proxies : **F10.7 is insufficient**
 - Also semi-empirical models that utilize CHIANTI (e.g. Woods et al, 2005)
- New and future instruments will continue and improve upon these measurements
 - New: GOES-16+ EXIS, Chandrayaan-2 XSM
 - Planned: INSPIRESAT/DAXSS
 - Proposed: SunCET, CUBIXSS
 - Replace the lost SDO/EVE/MEGS-A channel
 - Desire multi-vantage point observations
 - Take advantage of small instruments
 - CubeSats and “instruments of opportunity”
