

## GRAVITY WAVES

- Vertically propagating waves associated with the buoyancy restoring force in stably stratified fluids.
- Parcels oscillate parallel to phase lines and perpendicular to the direction of phase propagation.

$$\frac{d^2(\delta s)}{dt^2} = (N \cos \alpha)^2 \delta s$$

Parcel acceleration = Buoyancy force along  $\delta s$

General solution  $\delta s = \exp[\pm i(N \cos \alpha)t]$ .

Parcels oscillate at frequency  $N \cos \alpha$  where  $N$  is the buoyancy frequency,

$$N = \left( \frac{g}{\bar{\theta}} \frac{d\bar{\theta}}{dz} \right)^{1/2}.$$

Detailed analysis starting from the linearized fundamental fluid equations neglecting the Coriolis force gives the *dispersion relationship*:

$$(\omega - \bar{u}k)^2 = \hat{\omega}^2 = \frac{N^2 k^2}{[m^2 + k^2 + 1/(4H^2)]}$$

$\hat{\omega} = (\omega - \bar{u}k)$  is the *intrinsic frequency*

$k, m$  are the horizontal and vertical wavenumbers

$\bar{u}$  is the wind along the wave propagation direction

$H$  is the density scale height  $\rho = \rho_0 e^{-(z-z_0)/H}$

Can often approximate  $|m| \gg (2H)^{-1}$  giving

$$\hat{\omega} \simeq \pm \frac{Nk}{(m^2 + k^2)^{1/2}} \simeq \pm N \cos \alpha.$$

Define  $k > 0$ . Then eastward propagation for  $\hat{\omega} > 0$ ,  $\hat{c} = \hat{\omega}/k > 0$ , and lines of constant phase

$$\phi = kx + mz - \omega t = \text{Constant}$$

slope upward for  $m < 0$ .

Energy propagates at the *group velocity*

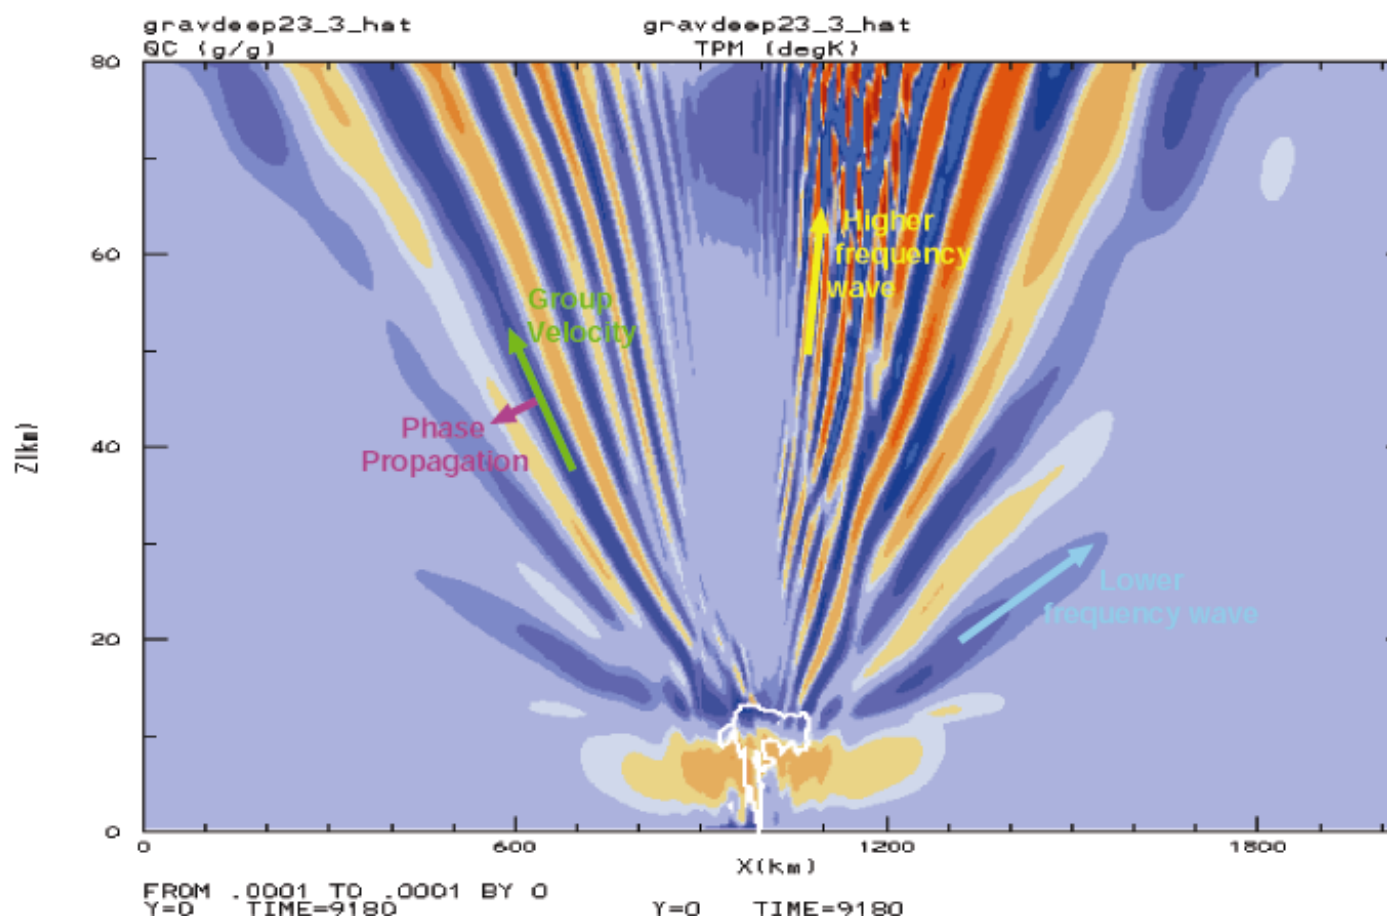

$$(c_{gx}, c_{gz}) = \left( \frac{\partial \hat{\omega}}{\partial k}, \frac{\partial \hat{\omega}}{\partial m} \right) = (\bar{u}, 0) \pm \frac{N}{(m^2 + k^2)^{3/2}} (-m, k)$$

So for eastward propagating waves (positive root) energy propagates upward and eastward relative to the mean flow. Since

$$\left| \frac{c_{gz}}{c_{gx} + \bar{u}} \right| = \left| \frac{k}{m} \right|$$

the group velocity vector is parallel to phase lines and perpendicular to phase propagation.

## Inertia-Gravity Waves

For low frequency gravity waves, the Coriolis force must be included, and the dispersion relationship becomes

$$\hat{\omega}^2 \simeq f^2 + N^2 k^2 / m^2$$

where  $f$  is the Coriolis parameter. The vertical to horizontal group velocity ratio

$$\left| \frac{c_{gz}}{c_{gx} + \bar{u}} \right| = \left| \frac{k}{m} \right| = (\hat{\omega}^2 - f^2)^{1/2} / N$$

So inertia-gravity waves propagate more closely to the horizontal than is the case for a pure gravity wave. Inertia-gravity waves also display horizontal wind perturbations both parallel and perpendicular to the propagation direction such that

$$\frac{v'}{u'} = -i \left( \frac{f}{\hat{\omega}} \right)$$

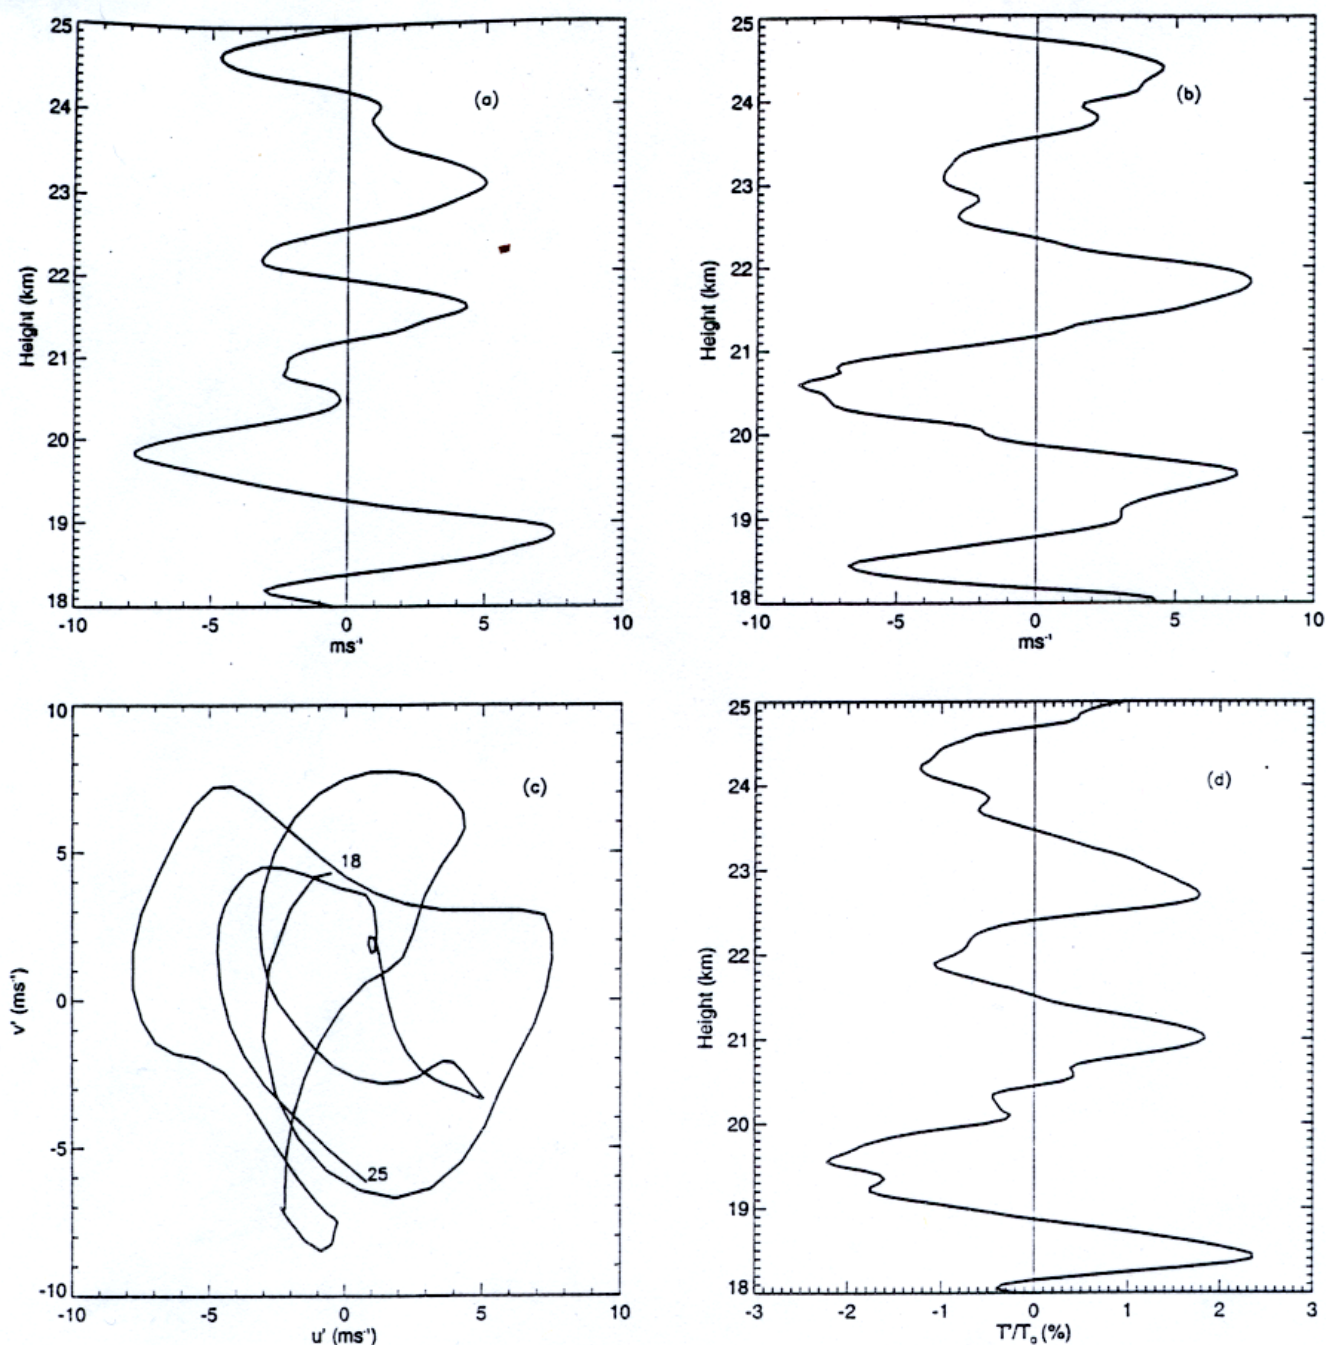

Vertical profiles plotted as  $u'(z)$  vs  $v'(z)$  (called a *hodograph*) trace an ellipse which becomes more circular as  $\hat{\omega} \rightarrow f$ .

$f$  is a lower limit for vertical propagation of gravity waves, and in general

$$|f| < |\hat{\omega}| < Nk / \sqrt{k^2 + 1/(4H^2)}.$$

$\hat{\omega} = f$  represents a critical level where the phase speed  $\hat{c} = \bar{u}$ .

$\hat{\omega} = Nk / \sqrt{k^2 + 1/(4H^2)}$  is a turning point where the vertical group velocity changes sign and energy is reflected downward.

**Figure 4.** Vertical profiles of (a) zonal and (b) meridional wind perturbations, (c) hodograph of the perturbation motions, and (d) percentage normalized temperature fluctuations for 5 February, 1995 at 2200 UT. In (c) the numbers 18 and 25 indicate the start and stop heights of the profiles

## Gravity Wave Breaking

Adiabatic waves, isentropes ( $\theta=\text{Constant}$ ) are material surfaces. Convective instability onset where

$$\frac{\partial\theta}{\partial z} = \frac{\partial\bar{\theta}}{\partial z} + \frac{\partial\theta'}{\partial z} = 0$$

where  $\bar{\theta}$  and  $\theta'$  are the background and disturbance potential temperature. The altitude where wave breaking will occur can be estimated from the linear solution.

The hydrostatic relationship in terms of the geopotential  $\Phi$

$$\frac{\partial\Phi}{\partial z} = RT/H = \frac{R}{H}\theta e^{-(z-z_0)R/c_p H}$$

Separating  $\Phi = \bar{\Phi} + \Phi'$  with

$$\Phi' = \Phi_0 \exp[(z - z_0)/(2H) + i(kx + mz - \omega t)]$$

and differentiating gives  $\partial\theta/\partial z = 0$  when

$$N^2 = m^2 \Phi_0 e^{z/2H}$$

So the breaking level is given by  $z_b \simeq 2H \ln|N^2 m^{-2} \Phi_0^{-1}|$  where  $\Phi_0$  is the wave amplitude at the reference level  $z_0$ .

For larger  $\Phi_0$  or larger  $m$  (smaller vertical wavelength), wave breaking is lower in the atmosphere. Since

$$m \simeq \pm \frac{N}{c - \bar{u}}$$

even small amplitude waves break as they approach a critical level.

## Gravity Wave Effects on the Atmosphere

Gravity waves carry momentum and energy vertically. Breaking or dissipation drives mean flow accelerations and can have vertical mixing and heating effects on the background atmosphere. Body force on the mean flow:

$$\bar{X} = -\frac{1}{\bar{\rho}} \frac{\partial M}{\partial z}$$

where  $M = \bar{\rho} \overline{(u'w')}(1 - f^2/\hat{\omega}^2)$ .  $M$  is  $-1$  times the gravity wave component of the EP-Flux.  $M > 0$  ( $< 0$ ) for eastward (westward) propagating waves.  $\bar{X}$  always in the direction of wave propagation. (Transience and nonlinearities can give rise to secondary wave emission from the breaking region.)

The EP-Flux is approximately conserved as a gravity wave propagates vertically. Then  $\bar{X} \propto \bar{\rho}^{-1}$  means that very small amplitude waves in the troposphere can have huge effects in the mesosphere.

Stratosphere winds are eastward in winter, westward in summer. These winds filter the gravity wave spectrum such that westward propagating waves break in the mesosphere, eastward in summer. Resulting drag forces, through Coriolis torques, drive a summer-to-winter meridional circulation,

$$\partial \bar{u} / \partial t - f \bar{v}^* = \bar{X}$$

## Atmospheric Gravity Wave Scales:

Horizontal wavelengths  $\sim 10 - 1000$ s km

Vertical wavelengths  $\sim 1 - 30$  km, and possibly longer

Periods:

Intrinsic frequency  $f < \hat{\omega} < N$

So  $2\pi/\hat{\omega} \sim 5$  min – several days

Observed from ground  $\omega = \hat{\omega} + \bar{u}k$

Can extend outside this range

Phase speeds  $\sim 0 - 100$  m/s, and possibly higher

## Gravity Waves in Vertical Shear $U(z)$

Simplified linear theory gives insight into the effects of background wind and stability variations on gravity waves as they propagate vertically:

$$\text{Intrinsic frequency} \quad \hat{\omega} = \omega_0 - kU(z) \sim \frac{N(z)k}{m(z)}$$

$$\text{Vertical wavelength} \quad \lambda_Z(z) \sim \hat{c}(z) \frac{2\pi}{N(z)}$$

$$\text{Intrinsic phase speed} \quad \hat{c} = c - U(z)$$

$$\text{Critical level: } \hat{c} = c - U(z) \rightarrow 0$$

horizontal wn =  $k$ , vertical wn =  $m$ , buoyancy freq =  $N$

**Observation of a gravity wave approaching a critical level [Sato and Yamada, 1994]:**

For this case  $c \sim 0$  so  $\lambda_Z \rightarrow 0$  as  $U(z) \rightarrow 0$ .

## Doppler-Shifting / Refraction Effects

Simulation of gravity waves generated by convection showing refraction of waves in the stratosphere :

Strong Stratospheric Shear

# Mean Flow $U(z)$ Effects: Doppler-shifting and Refraction

## Westward Shear

## Eastward Shear

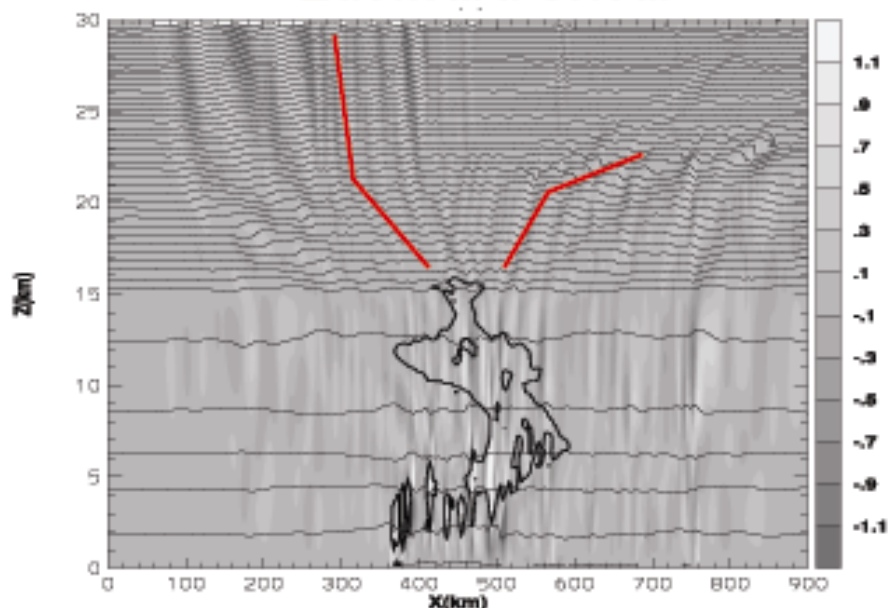

Figure 3. Two-dimensional simulations of tropical squall lines [Alexander and Holton, 1997]. The simulations are identical except for the shear in the stratosphere above 15 km altitude. (a) Case with easterly shear above 20 km. (b) Case with westerly shear above 20 km. The thick solid lines show the outline of the cloud water, the thin lines show potential temperature surfaces at 10K intervals, and the shading represents vertical velocity. The vertical velocity scale saturates at  $\pm 1.3$  m/s to show detail in the stratosphere. Peak values in the troposphere are actually larger at  $\pm 5$  m/s.

# CRISTA

Eckermann & Preusse (1999)

# Gravity Wave Sources

## 1. Topography

- only stationary waves  $c=0$
- mainly northern hemisphere winter
- note that the mesosphere effects depend on wave "saturation" assumptions

## 2. Jet instability

- again mostly winter hemisphere
- also more prevalent in northern hemisphere?

## 3. Convection

- can produce high phase speed waves
- will be common in the tropics & summertime extratropics
- large momentum fluxes have been observed

## 4. Other

shear generation, geostrophic adjustment, wave-wave interactions, secondary wave emission from wave breaking regions

# Global Distribution of Topographic Waves

Bacmeister's [1993] topographic ridge-finding algorithm

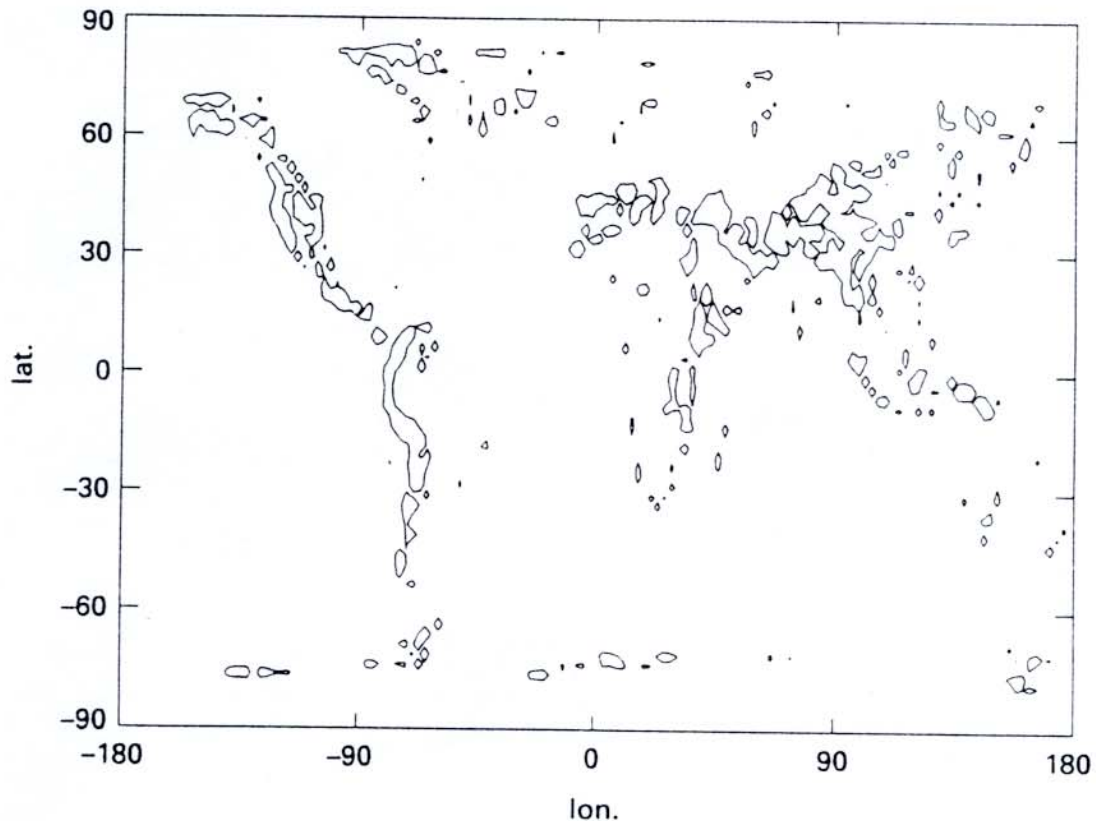

FIG. 3. Fractional area of  $2.5^\circ \times 2.5^\circ$  analysis boxes containing vertically propagating mountain waves  $S_w$ , which depends on  $a$ , as described in Eq. (4) of the text. Only 0.5 contour is drawn in the figure. This represents the maximum fractional area with waves allowed in the new parameterization.

- Topography is a geographically limited wave source.
- Most sources are in the Northern Hemisphere.
- Stationary ( $c=0$ ) mountain waves can only propagate through the stratosphere in winter.

- The characteristics of the waves generated in the stratosphere

VERTICAL VELOCITY POWER SPECTRA OF WAVES IN THE STRATOSPHERE:

The period of Latent Heating oscillations matches the dominant wave period in the stratosphere:

The dominant vertical wavelength in the wave spectrum is related to the depth of the latent heating in the storm.

The horizontal wavelength spectrum is broad and is shaped by nonlinear processes in the numerical model.

Chun and Baik [1998; 2002] Parameterization

FIG. 2. Perturbation vertical velocity field by (9). The parameters used are  $z_1 = 1.5$  km,  $z_r = 11$  km,  $z_c = 5$  km,  $N_1 = 0.01$  s<sup>-1</sup>,  $N_2 = 0.02$  s<sup>-1</sup>,  $U_r = 20$  m s<sup>-1</sup>,  $Q_0 = 1$  J kg<sup>-1</sup> s<sup>-1</sup>,  $a_1 = 10$  km,  $a_2 = 5$  km, and  $T_0 = 273$  K. The Richardson number associated with the basic flow is 9. The contour interval is 0.03 m s<sup>-1</sup>.

- Assumes convective heating  $Q$  is steady,  $dQ/dt=0$
- Waves are generated when there is a topside wind relative to the heating
- Response looks like mountain wave with  $c$ =storm propagation speed
- Models show this can be important for long-lived storms
- Observations suggest this as a viable mechanism for large-scale waves
